# 5 Probability: the mathematics of randomness

The theory of probability is the mathematician's description of random variation. This chapter introduces enough probability to serve as a minimum background for making formal statistical inferences.

## 5.1 (Discrete) random variables

The concept of a random variable is introduced in general terms and the special case of discrete data is considered.

#### 5.1.1 Random variables and distributions

It is helpful to think of data values as subject to chance influences. Chance is commonly introduced into the data collection process through

1. Random sampling technique

2. Megsurement error causes

3. changes in system conditions

**Definition 5.1.** A <u>random variable</u> is a quantity that (prior to observation) can be thought of as dependent on chance phenomena.

X = the value of a coin toss (heads or tails)

Z = the amount of torque required to 100s an the next both

T = the time you'll have to wait for next bus home

N = the number of defective widests in a manufacturing

process in a day

S = the number of unprovoked shark attacks off coast of

Enridg next year

**Definition 5.2.** A discrete random variable is one that has isolated or separated possible values (rather than a continuum of available outcomes).

**Definition 5.3.** A *continuous random variable* is one that can be idealized as having an entire (continuous) interval of numbers as its set of values.

Example 5.1 (Roll of a die).

List of possible values:

X = roll of 6-sided fair die - 1, a, 3, 4, 5, 6

Y = roll of 6-sided unfair die - 1, a, 3, 4, 5, 6

How to distinguish blun X and Y?

Probability of occurrence!

**Definition 5.4.** To specify a *probability distribution* for a random variable is to give its set of possible values and (in one way or another) consistently assign numbers between 0 and 1 - called *probabilities* - as measures of the likelihood that the various numerical values will occur **Example 5.2** (Roll of a die, cont'd).

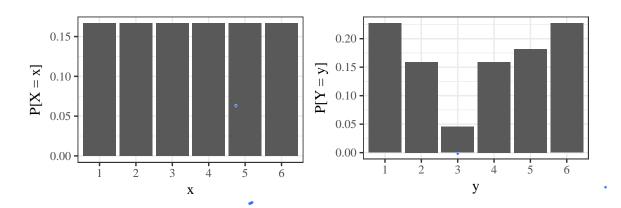

we expect a fair dice to (and on the number 3 roughly one out of every 6 tosses,  $P(x=3) = \frac{1}{6}$ 

suppose the unfail dice is weighted so that the number 3 only lands one out of every 22 tosses.

P[7=3] = 1

probability that X R.V. x 1 2 3 4 5 6 Fair discretely value x P[X=x] 1/6 1/6 1/6 1/6 1/6 1/6

$$\frac{y}{P[Y=y]} = \frac{1}{5/22} = \frac{3}{7/44} = \frac{4}{1/22} = \frac{5}{7/44} = \frac{5}{2/11} = \frac{6}{5/22}$$

$$\frac{s}{P[S=s]} = \frac{1}{6} \frac{1}{\pi^2} = \frac{1}{2^2} \frac{1}{\pi^2} = \frac{1}{3^2} \frac{1}{\pi^2} = \frac{1}{8^2} \frac{1}{\pi^2} = \cdots$$

### 5.1.2 Probability mass functions and cumulative distribution functions

The tool most often used to describe a discrete probability distribution is the *probability mass* function.

**Definition 5.5.** A probability mass function (pmf) for a discrete random variable X, having possible values  $x_1, x_2, \ldots$ , is a non-negative function f(x) with  $f(x_1) = P[X = x_1]$ , the probability that X takes the value  $x_1$ .

we can also write fx for the pmf of X and F5 for the pmf of 5.

Properties of a mathematically valid probability mass function:

2. 
$$\sum_{x} f(x) = 1$$
 (sum to 1)

**Example 5.4** (Torque). Let Z = the torque, rounded to the nearest integer, required to loosen the next bolt on an apparatus.

Calculate the following probabilities:

$$P(Z \le 14) = P[Z = 11 \text{ or } Z = 12 \text{ or } Z = 13 \text{ or } Z = 14]$$
  
=  $P[Z = 11] + P[Z = 12] + P[Z = 13] + P[Z = 14]$   
=  $f(11) + f(12) + f(13) + f(14)$   
=  $0.03 + 0.03 + 0.06 = 0.15$ 

$$P(Z > 16) = P[Z=17 \text{ or } Z=17 \text{ or } Z=17 \text{ or } Z=20]$$
  
=  $F(17) + F(18) + F(19) + F(20)$   
=  $0.12 + 0.20 + 0.15 + 0.03 = 0.5$ 

$$P(Z \text{ is even}) = P[Z=12 \text{ or } Z=14 \text{ or } Z=16 \text{ or } Z=18 \text{ or } Z=20]$$
  
=  $F(12) + F(14) + F(16) + F(18) + F(36)$   
=  $0.63 + 0.06 + 0.09 + 0.03 + 0.03 + 0.41$ 

$$P(Z \text{ in } \{15, 16, 18\}) = P[Z=15 \text{ or } Z=16 \text{ or } Z=18]$$

$$= f(15) + f(16) + f(18)$$

$$= 0.26 + 0.09 + 0.2 = 0.55$$

J

Another way of specifying a discrete probability distribution is sometimes used.

**Definition 5.6.** The cumulative probability distribution (cdf) for a random variable X is a function F(x) that for each number x gives the probability that X takes that value or a smaller one,  $F(x) = P[X \le x]$ .

Since (for discrete distributions) probabilities are calculated by summing values of f(x),

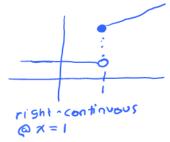

$$F(x) = P[X \le x] = \sum_{y \le x} f(y)$$

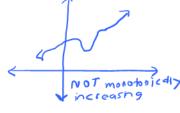

Properties of a mathematically valid cumulative distribution function:

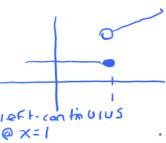

1. F(x) 30 for all real numbers x

- 2. F is monotonically increasing (when X increases, y either stays same or increases)
- 3. F(x) is right continuous
- 4. sim F(x)=0 and lim F(x)=1

jumps located at possible values and equal in size to the probabilities associated with these values.

**Example 5.5** (Torque, cont'd). Let Z = the torque, rounded to the nearest integer, required to loosen the next bolt on an apparatus.

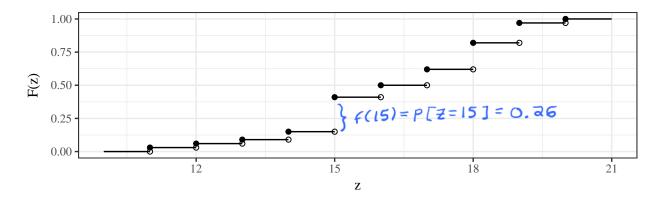

Figure 1: Cdf function for torques.

Calculate the following probabilities using the **cdf only**:

$$F(10.7) = P[Z \le 10.7] = P[Z \le 10] = 0$$

$$P(Z \le 15.5) = P(Z \le 15) = 0.41$$

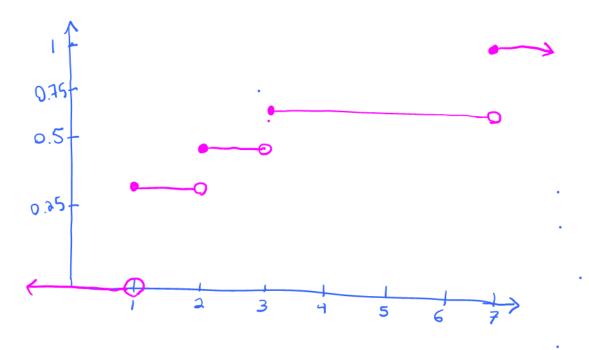

$$P(12.1 < Z \le 14) = P[Z = 13 \text{ or } Z = 14]$$

$$= f(14) + f(13) = [f(14) + f(13) + f(13) + f(13) + f(13)] - [f(14) + f(13)] + [f(14) + f(13) + f(13)] + [f(14) + f(13) + f(13) + f(13)] + [f(14) + f(13) + f(13) + f(13) + f(13) + [f(14) + f(13) + f(13) + f(13) + f(13)] + [f(14) + f(13) + f(13$$

**Example 5.6.** Say we have a random variable Q with pmf:

q	f(q)	F(8)
1	0.34	0.34
2	0.1	0.44
3	0.22	0.66
7	0.34	l

Draw the cdf.

## 5.1.3 Summaries

Almost all of the devices for describing relative frequency (empirical) distributions in Ch. 3 have versions that can describe (theoretical) probability distributions.

- 1.
- 2.
- 3.

**Definition 5.7.** The mean or expected value of a discrete random variable X is

$$EX = \sum_{x} x f(x)$$

**Example 5.7** (Roll of a die, cont'd). Calculate the expected value of a toss of a fair and unfair die.

**Example 5.8** (Torque, cont'd). Let Z = the torque, rounded to the nearest integer, required to loosen the next bolt on an apparatus.

Calculate the expected torque required to loosen the next bolt.

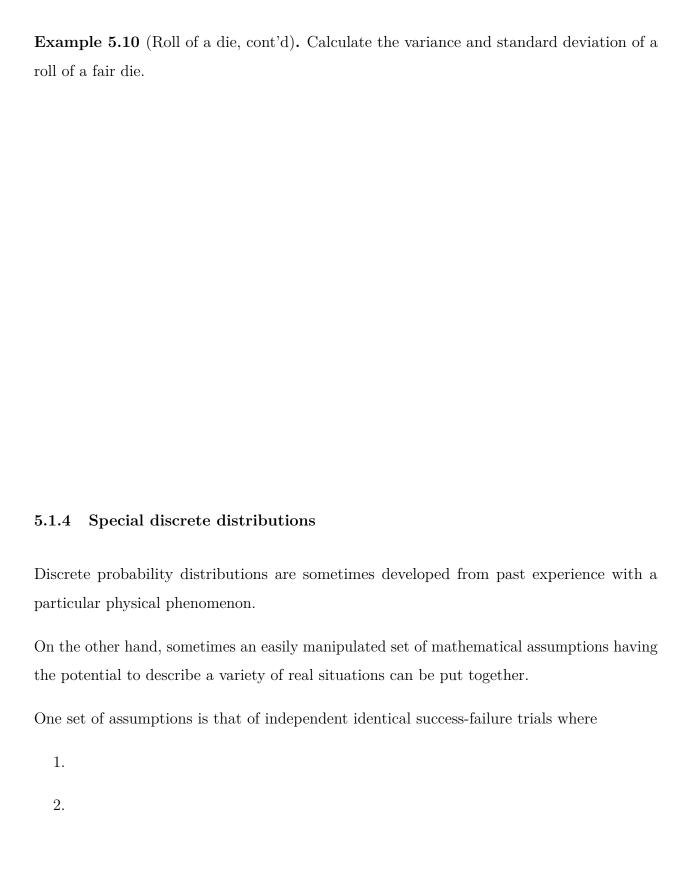

**Definition 5.8.** The *variance* of a discrete random variable X is

$$Var X = \sum_{x} (x - EX)^2 f(x) = \sum_{x} x^2 f(x) - (EX)^2.$$

The standard deviation of X is  $\sqrt{\operatorname{Var} X}$ .

**Example 5.9.** Say we have a random variable Q with pmf:

Calculate the variance and the standard deviation.

#### Consider a variable

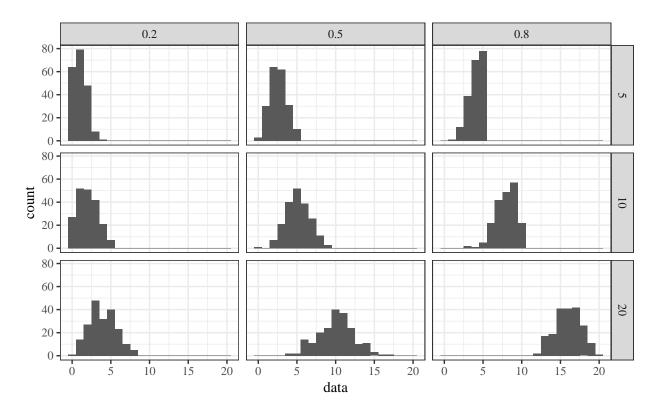

X = the number of successes in n independent identical success-failure trials

**Definition 5.9.** The binomial(n, p) distribution is a discrete probability distribution with pmf

$$f(x) = \begin{cases} \frac{n!}{x!(n-x)!} p^x (1-p)^{n-x} & x = 0, 1, \dots, n \\ 0 & \text{otherwise} \end{cases}$$

for n a positive integer and 0 .

Examples that could follow a binomial (n, p) distribution:

For X a binomial(n, p) random variable,

$$\mu = EX = \sum_{x=0}^{n} x \frac{n!}{x!(n-x)!} p^{x} (1-p)^{n-x} = np$$

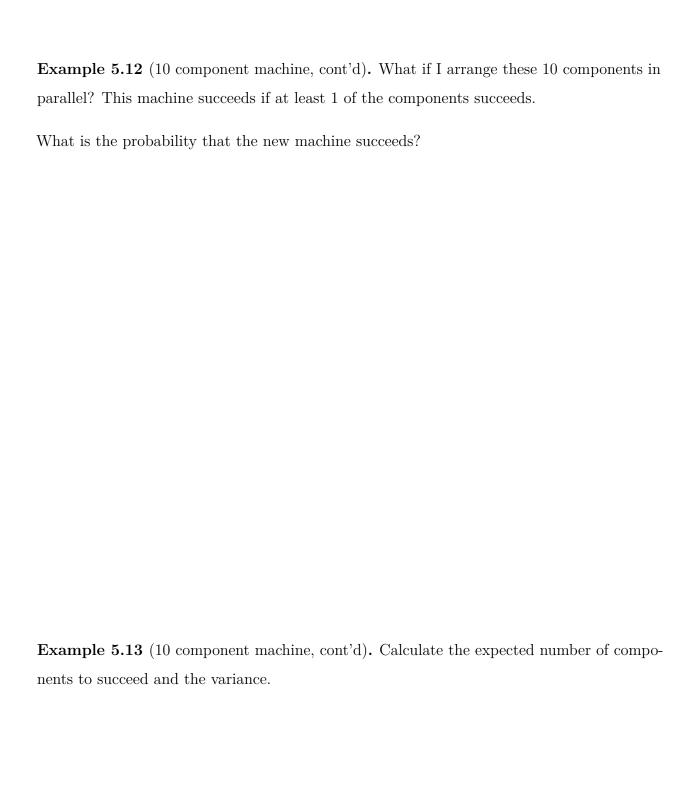

$$\sigma^{2} = VarX = \sum_{x=0}^{n} (x-np)^{2} \frac{n!}{x!(n-x)!} p^{x} (1-p)^{n-x} = np(1-p)$$

**Example 5.11** (10 component machine). Suppose you have a machine with 10 independent components in series. The machine only works if all the components work. Each component succeeds with probability p = 0.95 and fails with probability 1 - p = 0.05.

Let Y be the number of components that succeed in a given run of the machine. Then

$$Y \sim \text{Binomial}(n = 10, p = 0.95)$$

Question: what is the probability of the machine working properly?

#### Consider a variable

 $X=\,$  the number of trials required to first obtain a success result

**Definition 5.10.** The geometric(p) distribution is a discrete probability distribution with pmf

$$f(x) = \begin{cases} p(1-p)^{x-1} & x = 0, 1, \dots \\ 0 & \text{otherwise} \end{cases}$$

for 0 .

Examples that could follow a binomial (n, p) distribution:

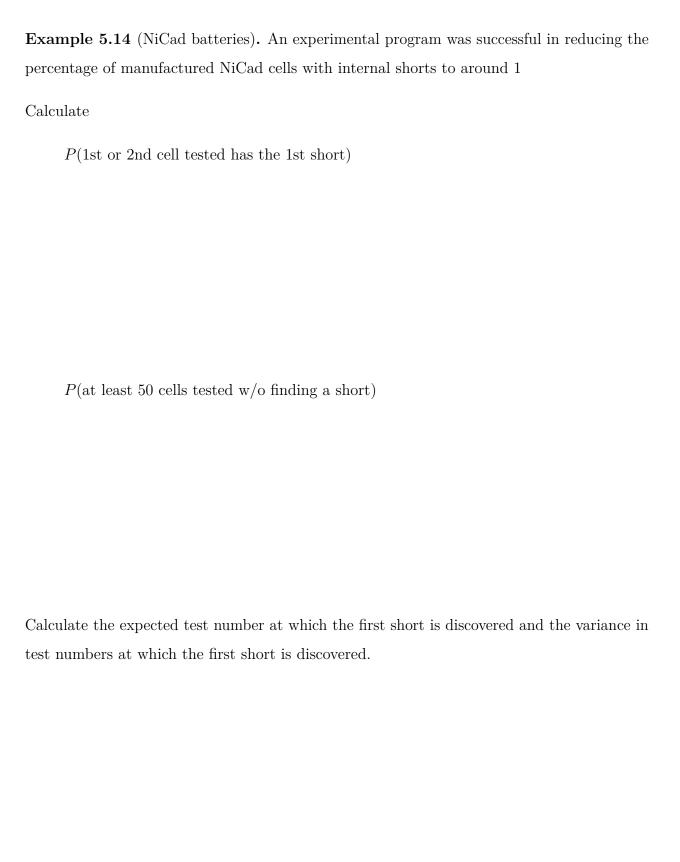

For X a geometric (p) random variable,

$$\mu = EX = \sum_{x=0}^{n} xp(1-p)^{x-1} = \frac{1}{p}$$

$$\sigma^{2} = VarX = \sum_{x=0}^{n} \left(x - \frac{1}{p}\right)^{2} p(1-p)^{x-1} = \frac{1-p}{p^{2}}$$

Cdf derivation:

It's often important to keep track of the total number of occurrences of some relatively rare phenomenon.

Consider a variable

X = the count of occurences of a phenomenon across a specified interval of time or space

**Definition 5.11.** The  $Poisson(\lambda)$  distribution is a discrete probability distribution with pmf

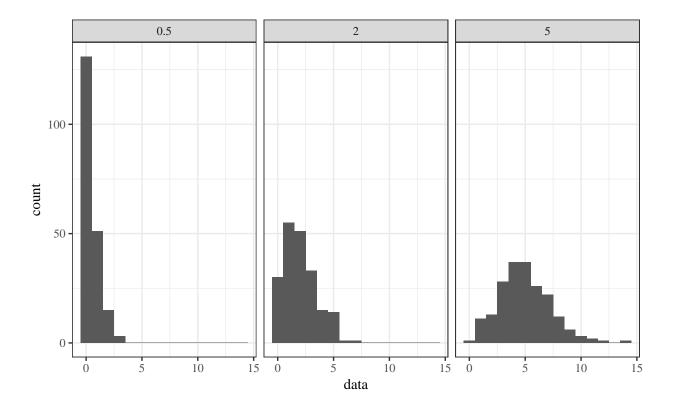

$$f(x) = \begin{cases} \frac{e^{-\lambda}\lambda^x}{x!} & x = 0, 1, \dots \\ 0 & \text{otherwise} \end{cases}$$

for  $\lambda > 0$ .

These occurrences must:

- 1.
- 2.
- 3.

Examples that could follow a Poisson( $\lambda$ ) distribution:

For X a Poisson( $\lambda$ ) random variable,

$$\mu = EX = \sum_{x=0}^{n} x \frac{e^{-\lambda} \lambda^{x}}{x!} = \lambda$$
$$\sigma^{2} = VarX = \sum_{x=0}^{n} (x - \lambda)^{2} \frac{e^{-\lambda} \lambda^{x}}{x!} = \lambda$$

**Example 5.15** (Arrivals at the library). Some students' data indicate that between 12:00 and 12:10pm on Monday through Wednesday, an average of around 125 students entered Parks Library at ISU. Consider modeling

M= the number of students entering the ISU library between 12:00 and 12:01pm next Tuesday

Model  $M \sim \text{Poisson}(\lambda)$ . What would a reasonable choice of  $\lambda$  be?

Under this model, the probability that between 10 and 15 students arrive at the library between 12:00 and 12:01 PM is:

**Example 5.16** (Shark attacks). Let X be the number of unprovoked shark attacks that will occur off the coast of Florida next year. Model  $X \sim \text{Poisson}(\lambda)$ . From the shark data at http://www.flmnh.ufl.edu/fish/sharks/statistics/FLactivity.htm, 246 unprovoked shark attacks occurred from 2000 to 2009.

What would a reasonable choice of  $\lambda$  be?

Under this model, calculate the following:

P[no attacks next year]

P[at least 5 attacks]

 $P[\mathrm{more\ than\ 10\ attacks}]$
