## 4 Describing relationships between variables

This chapter provides methods that address a more involved problem of describing relationships between variables and require more computation. We start with relationships between two variables and move on to more.

## 4.1 Fitting a line by least squares

We would like to use an equation to describe how a dependent (response) variable, y, changes in response to a change in one or more independent (experimental) variable(s), x.

#### 4.1.1 Line review

Recall a linear equation of the form y = mx + b

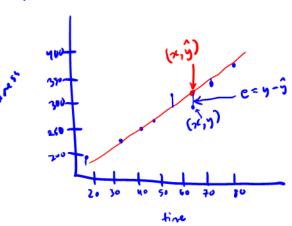

In statistics, we use the notation  $y = \beta_0 + \beta_1 x + \epsilon$  where we assume  $\beta_0$  and  $\beta_1$  are unknown parameters and  $\epsilon$  is some error.

The goal is to find estimates  $b_0$  and  $b_1$  for the parameters. (sending  $\hat{\beta}_0$  and  $\hat{\beta}_1$ )

**Example 4.1** (Plastic hardness). Eight batches of plastic are made. From each batch one test item is molded and its hardness, y, is measured at time x. The following are the 8 measurements and times:

| time     | 32  | 72  | 64  | 48  | 16  | 40    | 80  | 56  |
|----------|-----|-----|-----|-----|-----|-------|-----|-----|
| hardness | 230 | 323 | 298 | 255 | 199 | • 248 | 359 | 305 |

step 1: look at a scultiplet to detraile if a linea relation ship seems appropriate

Describe strength, direction, form:

· The is a strong, positive, linear relationship between the and hardness.

How do we find an equation for the line that best fits the data?

A straight line will not pass through every data point, so when we estimate a line, we will have predicted valves (g) instead of observed data (y)

The filled equation is 
$$\hat{y} = b_0 + b_1 x$$

**Definition 4.1.** A residual is the vertical distance between the actual data point and a fitted line,  $e = y - \hat{y}$ .

We choose the line that has the smallest residuals.

The *principle of least squares* provides a method of choosing a "best" line to describe the data.

**Definition 4.2.** To apply the *principle of least squares* in the fitting of an equation for y to an n-point data set, values of the equation parameters are chosen to minimize

$$\sum_{i=1}^{n} (y_i - \hat{y_i})^2$$

where  $y_1, y_2, \ldots, y_n$  are the observed responses and  $\hat{y}_1, \hat{y}_2, \ldots, \hat{y}_n$  are corresponding responses predicted or fitted by the equation.

We want to choose  $b_0$  and  $b_1$  to minimize

$$\sum_{i=1}^{n} (y_i - \hat{y}_i)^2 = \sum_{i=1}^{n} (y_i - b_0 - b_1 x_i)^2$$

$$0 = \frac{\partial}{\partial b_0} \sum_{i=1}^{n} (y_i - b_0 - b_1 x_i)^2 = -2 \sum_{i=1}^{n} (y_i - b_0 - b_1 x_i)$$

$$\Rightarrow 0 = \sum_{i=1}^{n} (y_i - b_0 - b_1 x_i)$$

 $0 - \frac{3}{3} \frac{1}{5} \left( 3! - 9^{0} - 9^{1} x! \right)_{5} = -5 \sum_{i=1}^{5} x! \left( 3! - 9^{0} - 9^{1} x! \right)$ 

$$\Rightarrow 0 = \sum_{i=1}^{n} x_i (y_i - b_0 - b_i x_i) \in$$

equati

Solving for  $b_0$  and  $b_1$ , we get

$$b_0 = \overline{y} - b_1 \overline{x}$$

$$b_1 = \frac{\sum (x_i - \overline{x})(y_i - \overline{x})}{\sum (x_i - \overline{x})^2} = \frac{\sum x_i y_i - \frac{1}{n} \sum x_i \sum y_i}{\sum x_i^2 - \frac{1}{n} (\sum x_i)^2}$$

**Example 4.2** (Plastic hardness, cont'd). Compute the least squares line for the data in Example 4.1.

| ardness       |                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                            |

$$b_1 = \frac{\sum x_i y_i - \frac{1}{n} \sum x_i \sum y_i}{\sum x_i^2 - \frac{1}{n} (\sum x_i)^2} = \frac{120832 - \frac{1}{8} (408)(2217)}{24000 - \frac{1}{8} (408)^2} = 2.433$$

$$b_0 = \bar{y} - b_1 \bar{x} = \frac{2217}{8} - 2.433 \frac{407}{8} = 153.06$$

y≈153.06+

Now we have the fitted line: y = 153.06 + 2.433 x

We can use this to 1) get interpretations of estimates and 2) compute a predicted/fitted value for a given x.

Q: What is the predicted hardness for time 
$$x=24$$
?  
 $\hat{y}=153.06+2.433(24) = 211.452$ 

ALVAYS went to put interpretactions in the context of your problem => replace everything in perentheses in a other problem

## Interpreting slope and intercept

• Intercept

When (se) is equal to O (inits), we expect (y) to be (b.) (units).

Interpreting the intercept is nonsense when

- 1. A value of 0 for x is not practical (i.e. measuring heights of adult humans)
  2. Extrapolation hold have to be used to get the predicted value of y
  (i.e. If we get a regative intercept for a measurement that connot be beg).

Note: this doesn't mean the intrupt is wrong! It's just not in trp retable.

**Example 4.3** (Plastic hardness, cont'd). Interpret the coefficients in the plastic hardness example. Is the interpretation of the intercept reasonable?

Slope (1, = 2.433) For every 1 hour increase in time, he expect the hardness by 2.433 units.

Introp (b = 153.06)

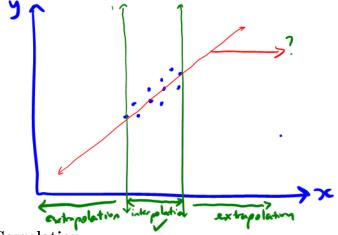

At time O hours, we expect the hardness to be (6,)

pe intrupt interpretation is NOT reasonable, because at the O Lours, the plantie is motten so expecting a hardness value of 153, 06 units is unrentistica

When making predictions, don't extrapolate.

**Definition 4.3.** Extrapolation is when a value of x beyond the range of our actual observations is used to find a predicted value for y. We don't know the behavior of the line beyond our collected data.

**Definition 4.4.** *Interpolation* is when a value of x within the range of our observations is used to find a predicted value for y.

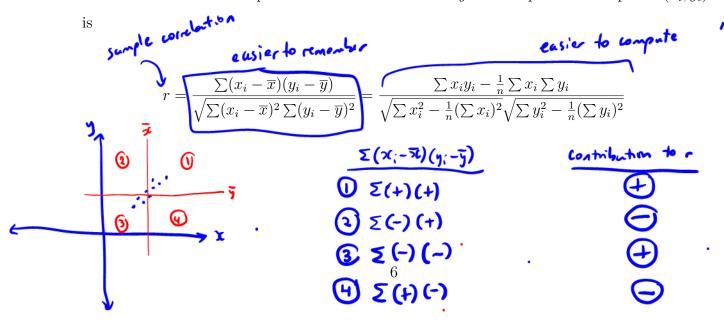

## 4.1.3 Correlation

Visually we can assess if a fitted line does a good job of fitting the data using a scatterplot. However, it is also helpful to have methods of quantifying the quality of that fit.

Definition 4.5. Correlation gives the strength and direction of the linear relationship (assume two variables.

**Definition 4.6.** The sample correlation between x and y in a sample of n data points  $(x_i, y_i)$ 

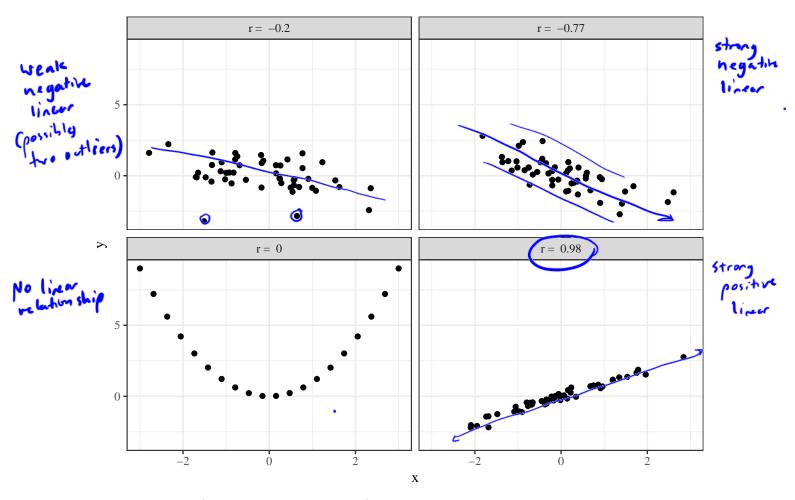

Properties of the sample correlation:

- -1 < r < 1
- r = -1 or r = 1 if all points lie exactly on the fitted line
- The closer r is to 0, the weaker the linear relationship; the closer it is to 1 or -1, the stronger the linear relationship.
- Negative r indications negative linear relationship; Positive r indications positive linear relationship
- (positive slope)
  Interpretation always need 3 things
  - 1. Strength (strong, moderate, weak)
  - 2. Direction (positive or negative)
  - 3. Form (linear relationship or no linear relationship)

Note:

① Strong = 
$$0.7 \le n \le 1$$
  $-1 \le n \le -0.7$   
moderate =  $0.3 \le n \le 0.7 -0.7 \le n \le -0.3$   
Weak =  $-0.3 \le n \le 0.3$ 

**Example 4.4** (Plastic hardness, cont'd). Compute and interpret the sample correlation for the plastic hardness example. Recall,

$$\sum x = 408, \sum y = 2217, \sum xy = 120832, \sum x^2 = 24000, \sum y^2 = 634069$$

$$r = \frac{\sum x_i y_i - \frac{1}{8} \sum x_i \sum y_i}{\sum x_i^2 - \frac{1}{8} (\sum x_i)^2 \sqrt{\sum y_i^2 - \frac{1}{8} (\sum y_i)^2}} = \frac{(20832 - \frac{1}{8} (408)(2217))}{\sqrt{24000 - \frac{1}{8} (408)^2} \sqrt{(34069 - \frac{1}{8}(2217)^2)}} = 0.9796$$

Julis a Ostrong, Opositive Dinear relationship between time and landness of plastic.

If linear model is appropriate, hun yis should look like Gi's except for small fluctuations explainable as rondom variation.

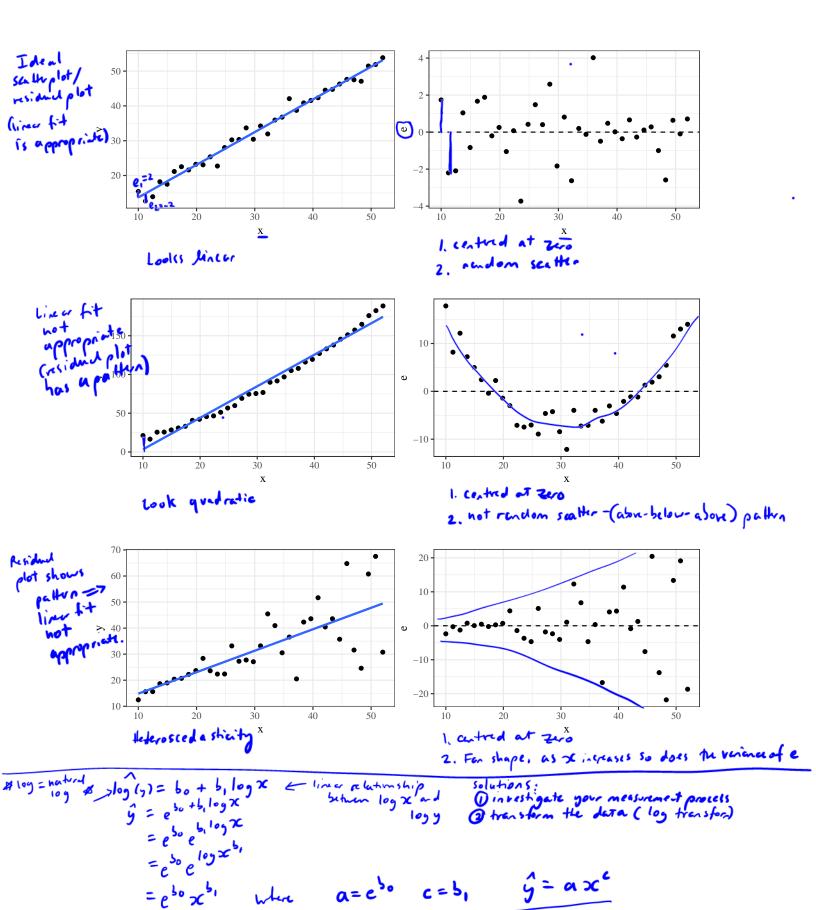

## 4.1.4 Assessing models

When modeling, it's important to assess the (1) validity and (2) usefulness of your model.  $e_i = y_i - \hat{y}_i = (b)$ 

To assess the validity of the model, we will look to the <u>residuals</u>. If the fitted equation is the good one, the residuals will be:

To check if these three things hold, we will use two plotting methods.

**Definition 4.7.** A *residual plot* is a plot of the residuals,  $e = y - \hat{y}$  vs. x (or  $\hat{y}$  in the case of multiple regression, Section 4.2).

bell shaped

To check if residuals have a Normal distribution,

Recall from Ch.3: Best way to check if data is normal is
the Normal QQ plot (plot orded data a gainst Provided normal quantiles)

Lyplot ordered residuals against hearted normal quantiles.

Look for straightline (close to) in Normal QQ plot of residuals.

To assess the usefulness of the model, we use  $\mathbb{R}^2$ , the coefficient of determination.

**Definition 4.8.** The *coefficient of determination*,  $R^2$ , is the proportion of variation in the response that is explained by the model.

Total amount of variation in the response

$$Var(y) = \frac{1}{n-1} \left( \frac{2}{3} \left( y_i - \overline{y} \right)^2 \right)$$

Sum of squares breakdown:

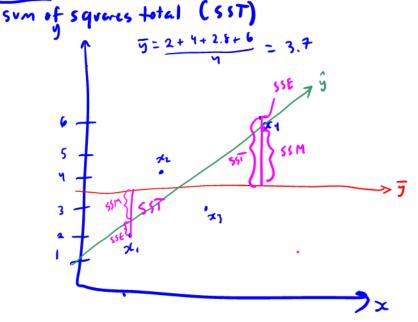

(sum of squeezs total measures variation of observed y; values around observed mean \$)

(sun of squares model measures the relationship between x and y)

(sum of squareserror measures factors over han the relationship when or and y)

$$SST = SSM + SSE$$

$$R^2 = \frac{SSM}{SST} = \frac{\Sigma(\hat{y_i} - \bar{y})^2}{\Sigma(y_i - \bar{y})^2} \bar{\Pi}$$

Properties of  $R^2$ :

whike 
$$\Gamma$$
 not just linear).  $n^2 = \frac{55M}{100}$ 

•  $R^2$  is used to assess the fit of other types of relationships as well (not just linear).

• Interpretation - fraction of raw variation in y accounted for by the fitted equation.

• 
$$0 \le R^2 \le 1$$

• The closer  $R^2$  is to 1, the better the model.

• For SLR, 
$$R^2=(r)^2$$
 [ONLY for simple like regression - y on >c]

**Example 4.5** (Plastic hardness, contd). Compute and interpret  $\mathbb{R}^2$  for the example of the relationship between plastic hardness and time.

$$R^2 = (r)^2 = (6.9796)^2 = 6.9597$$

## 4.1.5 Precautions

Precautions about Simple Linear Regression (SLR)

- r only measures linear relationships
- $\mathbb{R}^2$  and  $\mathbb{R}^2$  and  $\mathbb{R}^2$  and  $\mathbb{R}^2$  are detailed by a few unusual data points.
- · correlation does not recessfully mean Causation.

## 4.1.6 Using a computer

You can use JMP (or R) to fit a linear model. See BlackBoard for videos on fitting a model using JMP.

## 4.2 Fitting curves and surfaces by least squares

The basic ideas in Section 4.1 can be generalized to produce a powerful tool: multiple linear regression. (more than 2 explanatory variables, data appears to have a more complicated relationship than straight lines)

## 4.2.1 Polynomial regression

In the previous section, a straight line did a reasonable job of describing the relationship between time and plastic hardness. But what to do when there is not a linear relationship between variables?

Fit a more complicated equation

**Example 4.6** (Cylinders, pg. 132). B. Roth studied the compressive strength of concrete-like fly ash cylinders. These were made using various amounts of ammonium phosphate as an additive.

| ammonium.phosphate | strength | ammonium.phosphate | strength |
|--------------------|----------|--------------------|----------|
| 0                  | 1221     | 3                  | 1609     |
| 0                  | 1207     | 3                  | 1627     |
| 0                  | 1187     | 3                  | 1642     |
| 1                  | 1555     | 4                  | 1451     |
| 1                  | 1562     | 4                  | 1472     |
| 1                  | 1575     | 4                  | 1465     |
| 2                  | 1827     | 5                  | 1321     |
| 2                  | 1839     | 5                  | 1289     |
| 2                  | 1802     | 5                  | 1292     |

Table 1: Additive concentrations and compressive strengths for fly ash cylinders.

# step1: look at a scatteplot.

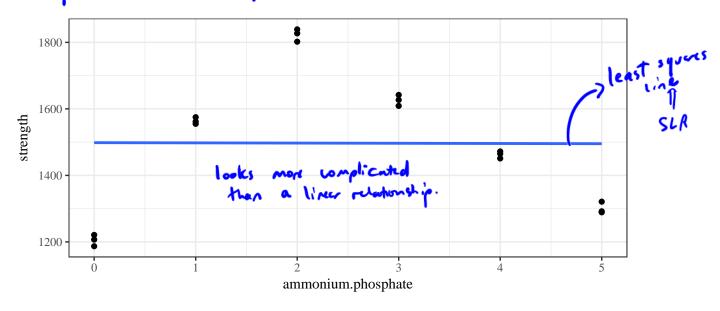

Figure 1: Scatterplot of compressive strength of concrete-like fly ash cylinders for various amounts of ammonium phosphate as an additive with a fitted line.

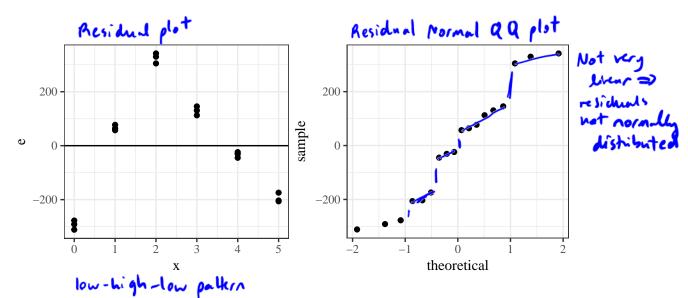

Figure 2: Residual plots for linear fit of cylinder compressive strength on amounts of ammonium phosphate.

Regident plat shows a pattern (not random scatte around zero)
Resident Normal QQ plat shows issues up normality => When fix is not a valid model

A natural generalization of the linear equation

$$y \approx \beta_0 + \beta_1 x$$

is the polynomial equation (curve fithing) with one y and one x vertable.

time slope parameters  $y \approx \beta_0 + \beta_1 x + \beta_2 x^2 + \dots + \beta_{p-1} x^{p-1}.$ 

The p coefficients are again estimated using the principle of least squares, where the function

$$S(b_0, \dots, b_{p-1}) = \sum_{i=1}^n (y_i - \hat{y})^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i - \dots - \beta_{p-1} x_i^{p-1})^2$$

must be minimized to find the estimates  $b_0, \ldots, b_{p-1}$ .

1. set pertiel derivative equal to 0 7 have a compater 2. solve for 60, 16,7-,5p-1 do this!

Example 4.7 (Cylinders, cont'd). The linear fit for the relationship between ammonium phosphate and compressive strength of cylinders was not great ( $R^2 = 2.8147436 \times 10^{-5}$ ). We can fit a quadratic model. ( type of polynomial model where  $\rho = 3$ )

$$y \approx \beta_0 + \beta_1 x + \beta_2 x^2$$

It does not appear that he have issues of validity with our model.

#### 4.2.2Multiple regression (surface fitting)

The next generalization from fitting a line or a polynomial curve is to use the same methods to summarize the effects of several different quantitative variables  $x_1, \ldots, x_{p-1}$  on a response y.

$$y \approx \beta_0 + \beta_1 x_1 + \cdots + \beta_{p-1} x_{p-1}$$
 (filling a surface)

Where we estimate  $\beta_0, \ldots, \beta_{p-1}$  using the least squares principle. The function

$$S(b_0,\ldots,b_{p-1})=\sum_{i=1}^n(y_i-\hat{y})^2=\sum_{i=1}^n(y_i-\beta_0-\beta_1x_{1,i}-\cdots-\beta_{p-1}x_{p-1,i})^2$$
 must be minimized to find the estimates  $b_0,\ldots,b_{p-1}$ .

1. Set partial derivatives of S to O 2. Solutor bos-, bp-1 (use a computer)

**Example 4.9** (New York rivers). Nitrogen content is a measure of river pollution. We have data from 20 New York state rivers concerning their nitrogen content as well as other characteristics. The goal is to find a relationship that explains the variability in nitrogen content for rivers in New York state.

| Variable    | Description                                                                   |  |  |
|-------------|-------------------------------------------------------------------------------|--|--|
| Y           | Mean nitrogen concentration (mg/liter) based on samples taken at regular      |  |  |
|             | intervals during the spring, summer, and fall months                          |  |  |
| $X_1$       | Agriculture: percentage of land area currently in agricultural use            |  |  |
| $X_1$ $X_2$ | Forest: percentage of forest land                                             |  |  |
| $X_3$ $X_4$ | Residential: percentage of land area in residential use                       |  |  |
| $X_4$       | Commercial/Industrial: percentage of land area in either commercial or indus- |  |  |
|             | trial use                                                                     |  |  |

Table 2: Variables present in the New York rivers dataset.

We will fit each of

$$\hat{y} = b_0 + b_1 x_1 \qquad \text{Nittogen } \sim \text{Agricultured old}$$
 
$$\hat{y} = b_0 + b_1 x_1 + b_2 x_2 + b_3 x_3 + b_4 x_4 \qquad \text{Nittogen } \sim \text{Agricultured of forest + }$$
 Residential + Conversal

 $\hat{y} = 0.9269 + 0.0119 x_1$ 

and evaluate fit quality.
